

E-Commerce Sales And Profit Report

Ecommerce sales dataset represents detailed transactional data captured from an online retail platform, where each row corresponds to an individual product purchased as part of a customer order. The dataset is designed to support comprehensive sales, customer, and product analysis by capturing key commercial attributes such as pricing, quantity, discounts, and order timing. It follows standard ecommerce data modeling practices, making it well suited for business intelligence tools like Power BI and for deriving meaningful insights related to revenue performance, customer behavior, and sales trends.

The OrderId column uniquely identifies each customer order and allows multiple products to be grouped under a single purchase, reflecting real-world shopping cart behavior. This column is essential for calculating total orders, average order value, and other order-level metrics. Customer-related columns, such as CustomerID or Customer Name, identify who placed the order and enable customer-level analysis, including repeat purchases and segmentation. Product-related fields, including Product Name and Product Category, describe what was purchased and support product performance and category-level revenue analysis.

Pricing information is captured through the Price column, which represents the per-unit price of a product before any discount is applied. The Quantity column indicates how many units of a product were purchased and, when combined with price, is used to calculate total revenue without discounts. The Discount column stores the percentage reduction applied to the product price and is useful for analyzing promotional effectiveness and discount impact. The FinalAmount column represents the discounted price (or net sales value) and reflects the actual amount charged to the customer, enabling accurate calculation of net revenue and profit impact.

Text Columns	Numerical Columns	Date Column
CustomerID Customer Name Customer City Customer State Seller ID Seller City Seller sate Category Order ID Payment Method Order Status Product ID Product Name Product Description Review Title	Price Discount Final amount Review score Quantity	Order date

The Navigator functions as the main navigation bar of the Analytics Dashboard, designed to help users quickly move between different sections of the sales report. It appears at the top of the dashboard as a horizontal row of rounded buttons enclosed in an orange outline, making it visually distinct and easy to locate. The navigation starts with an “Index” button, which typically serves as the home or overview page of the report. Following this are multiple report-specific tabs such as Report 1, Report 2, Cost Drill Through, Sales Drill Through, Location, Sales Location, Monthly Trends, Yearly Profit, Monthly Average, and Aging Analysis.

Slicers in a report are interactive filtering tools that allow users to control what data is displayed across charts, tables, and KPIs by selecting specific values such as time periods, regions, product categories, or customer segments. Instead of viewing all data at once, slicers enable focused analysis by narrowing the dataset to what is most relevant for the user’s question. When a slicer selection is made, all connected visuals update instantly, ensuring consistency across the report. This makes slicers especially useful in dashboards where multiple charts depend on the same dimensions, as they provide a simple and intuitive way to customize the view without changing the underlying report structure.

The impact of slicers on charts is substantial in business analysis. They transform static visuals into dynamic, user-driven insights by allowing decision-makers to compare scenarios, identify patterns within specific segments, and isolate performance issues quickly. For example, applying a date or region slicer can reveal seasonal trends, regional strengths, or underperforming products that might be hidden in aggregated data. Overall, slicers improve interactivity, enhance analytical flexibility, and empower users to explore data independently, leading to more accurate insights and better-informed business decisions.

The chart illustrates a tooltip-based product performance view integrated with a bar chart under the heading *Product Description*. On the left, the horizontal bars represent different products ranked by performance, allowing users to visually compare sales contribution across items. When a user hovers over a specific product bar—such as Standard Product Model B—a tooltip panel appears on the right, displaying key performance indicators related only to that selected product. This tooltip includes metrics like Total Revenue (3.21M), Total Orders (415), Profit Percentage (15.22%), and Previous Year Profit Percentage (15.95%), along with the product name highlighted at the bottom. The design ensures that detailed insights are shown contextually without overcrowding the main visual.

From a business analysis perspective, this tooltip is used to support quick, on-the-spot decision-making. Analysts and managers can instantly evaluate how a specific product is performing in terms of revenue, order volume, and profitability, and also compare current profit margins with the previous year. This helps in identifying high-performing products, detecting margin pressure, and understanding whether growth is sustainable or declining. Tooltips like this enhance dashboard interactivity by enabling users to explore detailed product-level insights without navigating away or running separate reports, making them especially valuable for product performance reviews, pricing decisions, and profitability analysis.

The Monthly Analysis image is used to closely examine sales performance on a month-by-month basis, allowing decision-makers to identify short-term trends, seasonality, and sudden changes in performance. When accessed through drill-through, users can click on a high-level metric (such as total sales or profit) and break it down into individual months, products, or regions. This view helps businesses understand which months are driving revenue growth and which months underperform, making it easier to plan promotions, manage inventory, and align staffing or marketing efforts with demand cycles. It is especially valuable for detecting seasonal spikes or drops that might be hidden in yearly summaries.

The Yearly Profit image focuses on long-term profitability trends by comparing profits across different years. Through drill-through functionality, users can move from a summarized profit figure into detailed yearly breakdowns, including cost, revenue, and margin components. This analysis helps businesses evaluate whether profitability is improving or declining over time and whether growth is sustainable or driven by short-term factors. It supports strategic decisions such as budgeting, investment planning, pricing strategies, and cost control by showing how profit performance evolves year over year rather than just focusing on sales volume.

The Monthly Moving Average image is designed to smooth out short-term fluctuations in sales or profit data to reveal the underlying trend more clearly. When used through drill-through, analysts can start from a general performance metric and examine how averages shift over consecutive months. This is particularly useful in volatile markets where individual months may show sharp ups and downs. Businesses use this view to reduce noise in the data, forecast

future performance more accurately, and make informed decisions without overreacting to temporary spikes or dips. It is commonly applied in demand forecasting, sales planning, and performance monitoring.

The Aging Analysis image is critical for managing receivables and understanding customer payment behavior. Through drill-through, users can move from a summarized aging category (such as total outstanding balance) into detailed buckets like 0–30 days, 31–60 days, 61–90 days, and overdue amounts by customer or invoice. This analysis helps businesses assess credit risk, monitor cash flow health, and identify customers who consistently delay payments. It supports proactive actions such as follow-ups, credit limit adjustments, or revised payment terms, ultimately helping the business reduce bad debts and maintain financial stability.

The map shows a location-based map visual used in a report to analyze data geographically, combined with drill-through functionality. The map highlights different U.S. states using distinct colors, allowing users to visually compare performance across locations such as states or regions. A legend at the top lists multiple states, helping users identify and filter specific locations. By right-clicking on a selected state—such as the highlighted region in North America—a context menu appears that includes options like *Include*, *Exclude*, and most importantly *Drill through*. This enables users to move from a high-level geographic overview into more detailed report pages such as Customer Drill Through, Seller Drill Through, Location, or Seller Location, all while carrying the selected state as a filter.

From a business analysis perspective, this type of visual and interaction is highly impactful because it connects where performance happens with why it happens. Managers can start by identifying high- or low-performing regions on the map and then drill through to explore underlying factors such as customer behavior, seller performance, or regional sales trends. This supports location-based decision-making, including regional marketing strategies, inventory distribution, expansion planning, and performance benchmarking.

The dashboard displays a table of monthly revenue and orders by state, along with six bar charts showing total revenue and orders by month for each state.

Month Name	SellerState	Total Revenue	Total Orders
Jan	Alabama	1,03,260.21	12
Jan	Alaska	55,040.99	6
Jan	Arizona	70,991.73	7
Jan	Arkansas	35,481.43	9
Jan	California	98,776.46	11
Jan	Colorado	37,344.74	5
Jan	Connecticut	40,728.20	7
Jan	Delaware	1,25,209.27	14
Jan	Florida	1,11,792.44	12
Jan	Georgia	24,373.67	6
Jan	Hawaii	65,197.67	8
Jan	Idaho	1,31,400.29	13
Jan	Illinois	22,047.43	7
Jan	Indiana	92,857.68	13
Jan	Iowa	80,845.45	8
Jan	Kansas	52,759.15	6
Jan	Kentucky	5,153.14	6
Jan	Louisiana	31,435.26	8
Jan	Maine	71,152.52	9
Jan	Maryland	89,109.22	11
Jan	Massachusetts	49,350.31	6
Jan	Michigan	86,950.31	10
Jan	Minnesota	1,00,202.61	14
Total		3,83,43,453.27	3878

The bar charts show Total Revenue and Total Orders by Month Name and SellerState for Alabama, Alaska, Arizona, Arkansas, California, and Colorado. The Y-axis represents Total Revenue (0K to 200K) and Total Orders (0K to 20K). The X-axis represents Month Name (Jan to Oct).

Payment Details

The donut chart displays the distribution of payment methods. The data is as follows:

Payment Method	Value	Percentage
Bank	7.38M	19.24%
Card	7.77M	20.26%
Other	7.64M	19.92%
Other	0M	0%
Other	0M	0%
Other	0M	0%
Other	0M	0%
Other	0M	0%

The summary table provides additional details:

Payment Details	
2.17M Sum of...	2.56M Sum of Price
39176.50K% Discount	3K Quantity
Wallet First PaymentMethod	

The Payment Details visual provides a clear overview of how customers complete their purchases by analyzing sales distribution across different payment methods. The donut (pie) chart represents the contribution of each payment method—such as Credit Card, Debit Card, UPI, Wallet, or other modes—to the overall sales value. Each segment shows the total monetary value and percentage share, allowing stakeholders to quickly identify the most preferred and revenue-generating payment methods. This visual helps the business understand customer payment preferences and optimize payment channel strategies.

The visual is enhanced with a selection slicer that allows users to dynamically filter the data based on a chosen payment method. When a payment method is selected, all related KPI cards and values update accordingly, showing the selected method’s total price, discount amount, final sales value, and total quantity. This interaction enables focused analysis of individual payment methods rather than viewing only aggregated data.

A custom tooltip is implemented on the donut chart to provide additional insights without overcrowding the visual. When users hover over a payment method segment, the tooltip displays detailed metrics such as total price, total discount applied, final amount after discount, and the selected payment method name. This allows users to access deeper information instantly while maintaining a clean and intuitive dashboard layout.

From a business perspective, this visual supports better decision-making by helping teams identify which payment methods drive the highest revenue, which ones attract higher discounts, and how customer purchasing behavior varies by payment channel. These insights can be used to improve payment partnerships, optimize promotional offers, reduce transaction costs, and enhance the overall customer checkout experience.

The Order Status is designed to show how orders progress through different stages such as *Completed*, *Pending*, *Shipped*, *Cancelled*, or *Returned*, giving a clear operational view of the order lifecycle. The visual is usually presented using charts like bars, columns, or donut charts to make it easy to compare the volume or percentage of orders in each status. This allows users to quickly identify bottlenecks—for example, a high number of pending or delayed orders—or assess how efficiently orders are being fulfilled. By visually summarizing order flow, the image helps stakeholders monitor service performance and operational health at a glance.

The tooltip within the Order Status image adds an important layer of detail without overcrowding the chart. When users hover over a specific order status, the tooltip typically displays supporting metrics such as total orders, revenue impact, average delivery time, or comparison with previous periods. This helps analysts immediately understand the business impact of each status—for instance, how much revenue is tied up in pending orders or lost due to cancellations. From a business analysis perspective, this combination of visual and tooltip supports faster root-cause analysis, improves order management decisions, enhances customer satisfaction tracking, and enables proactive actions to reduce delays, cancellations, or fulfillment issues.

The Review of Product image is used to present customer feedback and satisfaction levels for products in a clear, visual manner, often through charts such as bar graphs, rating distributions, or sentiment indicators. This image typically shows how products are rated—such as the number of positive, neutral, and negative reviews or average star ratings—allowing users to quickly compare customer perception across products. By visualizing reviews

alongside product names or categories, the report highlights which products are well-received and which may be facing quality, usability, or expectation issues. This makes it easier for business users to connect product performance not just to sales, but also to customer experience.

The tooltip in the Review of Product image provides deeper insight when users hover over a specific product or rating segment. It usually displays details such as total number of reviews, average rating score, percentage of positive versus negative feedback, and sometimes recent review trends. This added context helps analysts understand whether a low rating is based on a small sample or a significant customer concern. From a business analysis perspective, this image and its tooltip support informed decisions around product improvements, quality control, pricing adjustments, and marketing strategies by combining customer sentiment with quantitative performance data, ultimately helping businesses enhance customer satisfaction and brand trust.

The graph titled “MOM% and PY Profit% by Month Name” illustrates the month-over-month (MoM) profit growth trend while comparing the current month’s performance against the previous year’s profit percentage. The shaded area shows how MoM profit growth fluctuates across months, reflecting natural seasonality and volatility in business performance. A highlighted indicator shows the current MoM profit growth at 0.87%, compared to a previous-year profit benchmark of 0.17%. Although the MoM growth is positive and higher than the previous year’s percentage, the large variance displayed highlights how sensitive monthly performance can be when compared to historical benchmarks.

When this graph is compared with the earlier visualization that used this year’s profit percentage as the benchmark, a clearer business story emerges. In the “this year” comparison, the same MoM growth of 0.87% appeared significantly lower than the year-to-date profit percentage (16.94%), signaling a slowdown in momentum and indicating that the

current month is underperforming relative to overall annual performance. This view is especially useful for internal performance management, as it helps leadership assess whether the business is on track to meet annual profitability goals and whether corrective actions are needed within the same financial year.

The left graph (YOY% and Profit % by Year) shows the overall year-over-year profit growth compared against a target profit benchmark. The highlighted value of -3.30% indicates that total profit has declined compared to the previous year. When measured against the goal of 17.24% , the large negative variance clearly signals that the business is underperforming at an annual level. From a business standpoint, this is a critical warning indicator. It suggests that despite any short-term improvements during the year, the cumulative effect of factors such as increased costs, pricing pressure, lower demand, or operational inefficiencies has resulted in a net decline in profitability. This view is particularly important for executives, investors, and finance teams because it reflects the overall financial health and sustainability of the business.

The right graph (YOY% and PY Profit% by Month Name) provides a more granular, month-by-month year-over-year comparison against the previous year's profit percentage. Here, the highlighted value of 24.63% , which exceeds the previous year benchmark of 0.17% , indicates strong improvement in certain months compared to the same periods last year. From a business perspective, this reveals that while the full-year performance is negative, the business has recently shown positive momentum and recovery at the operational level. It helps identify months where strategies such as cost control, improved sales performance, or operational efficiencies are starting to deliver results.

The Customer State presents a focused, state-level view of customer distribution and performance, usually displayed using visuals such as bar charts, tables, or maps filtered to a selected state. This image shows key customer-related metrics like total customers, number of orders, sales revenue, and customer contribution by category or segment within that state.

When accessed through drill-through from a location or summary visual, the selected state is automatically applied as a filter, ensuring that all data shown relates only to customers from that specific region. This makes the visual clear and context-driven, helping users immediately understand how customers in a particular state are performing. It also reponds to the slicer Selection and changes according to the selected measure.

The drill-through functionality in the Customer State image allows users to go even deeper by clicking on a customer segment, category, or metric to view detailed customer-level information such as individual customer names, order counts, purchase values, or buying patterns. This supports business analysis by enabling regional customer profiling, identifying high-value or repeat customers, and uncovering state-specific preferences or demand trends. Overall, the Customer State image helps businesses tailor marketing strategies, optimize regional sales efforts, and improve customer engagement by transforming high-level geographic insights into actionable, customer-centric intelligence.

The Seller State provides a state-level view of seller or vendor performance, showing how different sellers contribute to sales and order fulfillment within a selected state. This image is typically displayed using visuals such as bar charts, tables, or KPIs that rank sellers based on metrics like total sales, order volume, profit, or fulfillment rate. When accessed through drill-through from the Location map or summary visuals, the selected state is automatically applied as a filter, ensuring that only sellers operating in that state are displayed. This makes the analysis highly contextual and allows users to clearly see which sellers are driving performance and which may be underperforming in that region. It also changes according to the selection slicer.

The drill-through and slicer interaction further enhances the usefulness of the Seller State image. When users apply slicers—such as time period, product category, or order status—the visuals respond instantly, updating seller performance based on the selected criteria. Drill-through may also allow users to click on a specific seller to view deeper details like product mix, customer reach, or profitability trends. From a business analysis perspective, this image helps evaluate regional seller effectiveness, optimize vendor partnerships, manage supply chain performance, and support data-driven decisions related to seller selection, regional expansion, and operational improvements.

The Top 5 States is designed to highlight the highest-performing states based on key business metrics such as total sales, revenue, profit, or order volume. This image is typically shown using a bar or column chart where each bar represents a state, making it easy to compare performance at a glance. The chart dynamically responds to slicer selections such as date range, product category, or order status, meaning the top five states update automatically based on the selected filters. This ensures that users always see the most relevant and current ranking, whether they are analyzing performance for a specific time period or a particular segment of the business.

The tooltip in the Top 5 States image provides additional detail when users hover over a state bar. It usually displays supporting metrics such as exact sales value, number of orders, profit margin, or comparison with previous periods, giving more context behind why a state appears in the top five. This interaction helps analysts quickly assess the strength and sustainability of each state's performance without overcrowding the chart. From a business analysis perspective, this image supports strategic decisions such as regional investment, targeted marketing, resource allocation, and expansion planning by clearly identifying top-performing regions and explaining the drivers behind their success.

The Top 5 Seller States highlights the states where sellers generate the highest performance, typically based on metrics such as total sales, revenue, profit, or order volume. This image is commonly displayed using a bar or column chart, with each bar representing a state ranked by seller contribution. The visual dynamically responds to slicer selections—such as time period, product category, or order status—so the top five seller states automatically update according to the selected filters. This ensures the ranking always reflects the current business context and allows users to analyze seller performance under different scenarios.

The tooltip in the Top 5 Seller States adds deeper insight when users hover over a state. It usually shows detailed metrics like total seller revenue, number of active sellers, total orders, and profit margins for that state. This helps users understand not just which states rank in the top five, but also *why* they perform well. From a business analysis perspective, this image supports decisions related to seller expansion, regional sales strategies, logistics planning, and marketplace optimization by identifying high-performing seller regions and revealing the underlying drivers of their success.

The Top 5 Products is used to showcase the five highest-performing products within selected states, usually based on key measures such as sales value, order quantity, or profit. This image is typically presented using a bar or column chart where each bar represents a product ranked by performance. The visual responds dynamically to slicer selections like state, time period, product category, or order status, ensuring that the top five products displayed always reflect the user's current filters. This allows analysts to quickly see which products are driving performance in a specific region or under specific business conditions.

The tooltip in the Top 5 Products provides additional context when users hover over a product bar. It commonly displays detailed metrics such as total sales, number of orders, profit margin, and sometimes comparison with previous periods or other states. This helps users understand the strength and consistency of each product's performance without cluttering the chart. From a business analysis perspective, this image supports product-level decision-making such as regional product prioritization, inventory planning, targeted promotions, and pricing strategies by clearly identifying top-performing products and explaining the factors behind their success.

The Total Revenue and Total Orders image serves as a high-level summary view that presents the most critical business performance indicators in a simple and prominent format. These metrics are usually displayed using KPI cards or tiles, where Total Revenue shows the overall income generated and Total Orders reflects the volume of transactions within the selected period or filters. The values update dynamically based on slicer selections such as date range, state, product, or seller, ensuring that users are always viewing the most relevant snapshot of business performance. This visual is designed for quick interpretation, often positioned at the top or end of the report to provide an immediate understanding of overall results.

From a business analysis perspective, this image plays a key role in performance monitoring and decision-making. Total Revenue helps assess financial success and growth, while Total Orders provides insight into customer demand and sales activity. When analyzed together, these metrics allow businesses to evaluate trends such as whether revenue growth is driven by higher order volume or increased order value. This information supports strategic decisions related to pricing, marketing effectiveness, sales forecasting, and operational planning, making the Total Revenue and Total Orders image an essential component for executive-level reporting and business health assessment.
